## ABSTRACT

The infrared-active vibration-rotation fundamentals of sulfur dioxide have been measured with moderately high spectral resolution. Quantum number assignments have been made for spectral lines from  $J = 0$  to 57, by comparison with theoretically computed spectra which include the effects of centrifugal distortion. The following values for the band centers have been determined:  $v_1^o = 1151.65 \pm 0.10 \text{ cm}^{-1}$ ,  $v_2^o = 517.75 \pm 0.10 \text{ cm}^{-1}$ , and  $v_3^o = 1362.00 \pm 0.10 \text{ cm}^{-1}$ . Intensities of the observed lines have also been computed. Dipole moment derivatives have been obtained.

## I. INTRODUCTION

Nearly twenty years have passed since the important systematic observation of 17 infrared-active vibration-rotation bands of sulfur dioxide by Shelton, Nielsen, and Fletcher.<sup>1</sup> In that work on  $^{32}\text{S}^{16}\text{O}_2$ , unfavorable energy and detector conditions in several spectral regions necessitated the use of slits ranging from 0.30 to 2.00  $\text{cm}^{-1}$ . Consequently, it was not possible to resolve individual transitions, and only sub-branches were assigned.

More recently, high-resolution microwave and far-infrared spectra of  $\text{SO}_2$  arising from pure rotational transitions in the ground and excited states have been obtained.<sup>2-7</sup> From analyses of these spectra, accurate values of rotational and centrifugal distortion constants are available. Hinkley *et al.*<sup>8</sup> have now observed some individual transitions of the  $v_1$  vibration-rotation bands of  $\text{SO}_2$  using tunable semiconductor lasers with very high resolution.<sup>9</sup> Prior to our knowledge of this most recent work,<sup>8,9</sup> we undertook moderately high-resolution studies of all three infrared-active fundamentals of  $^{32}\text{S}^{16}\text{O}_2$  in order to assign as many individual vibration-rotation transitions as possible.

The experimental details for our absorption spectra are discussed in the next Section. In Section III, asymmetric rotor theory is reviewed briefly. Then we present our results in the form of measured spectra, and tabulated experimental and theoretical positions for more than twelve hundred lines. In the last Section, we discuss future studies in which certain experimental and theoretical advances may be expected. Finally, we consider the potential application of our results to laser science and to air pollution problems.

## II. EXPERIMENTAL DETAILS

The anhydrous grade  $^{32}\text{S}^{16}\text{O}_2$  gas sample was obtained from Matheson Gas Products. The stated purity of the sample was 99.98% by weight; with 50, 10, and 30 p.p.m. maxima of  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{SO}_4$ , and non-volatiles, resp. A Perkin-Elmer Model 225 Grating Infrared Spectrophotometer, equipped with an f/5 fore monochromator for pre-dispersion of the radiation, was

used to record the spectra. A 150 lines/mm grating was employed in the first order for the 1100 to 1400  $\text{cm}^{-1}$  region, and a 30 lines/mm grating in the second order for the 475 to 600  $\text{cm}^{-1}$  region. A servo-controlled slit program was utilized to provide constant energy to the thermopile detector. A filtered Sola transformer served as a power supply which minimized external electrical noise and provided a constant voltage to the spectrophotometer.

Before each run, the alignment of the Littrow mount in the fore monochromator, and the position of the thermopile relative to the emerging radiation source were precisely adjusted to maximize signal strength. All scans were recorded on a Model 225 Auxiliary Recorder at a speed of  $0.5 \text{ cm}^{-1}/\text{min}$  at suitable scale expansions. A minimum of five runs was taken for each vibration-rotation band. The best two runs with respect to reproducibility, resolution, and noise level were selected for the theoretical analysis of each band.

Two 10-cm absorption cells, one with NaCl and the other with KBr windows, were used. The cells were placed in the sample compartment for one hour prior to each run in order to stabilize (at approximately 315°K) the temperature increase caused by heating from the Globar radiation source.

The details of our experimental conditions are summarized in Table I. Several runs of  $v_2$  were also made using cells with KRS-5 windows. However, it was found that substantially higher energy was available with the KBr windows due to their lower refractive index; hence, narrower slits could be used. For calibration purposes, spectra with resolution comparable to that achieved in the present work were chosen. In spite of the larger slit width and lower dispersion in our measurements of  $v_2$ , the absolute accuracy in its line positions is the same as that for  $v_1$  and  $v_3$  because of a better intercomparison with the calibration lines.<sup>11</sup>

### III. THEORETICAL ANALYSIS

The sulfur dioxide molecule is an asymmetric rotor with  $\text{C}_{2v}$  symmetry,<sup>12</sup> whose bond length and bond angle are 1.4308 Å and  $119^{\circ}20'$ , resp.<sup>7</sup> As the theory of asymmetric top spectra is well known,<sup>12,13</sup> only a brief review pertinent to present work will be given. From Kivelson and Wilson's<sup>14</sup> theory for first-order centrifugal distortion, with the inclusion of second-order terms<sup>15</sup> up to  $\langle P_z^4 \rangle$ , the energy expression is

$$\begin{aligned}
E = E_r - [D_J + 2R_6]J^2(J+1)^2 - [D_{JK} - 4R_6]J(J+1)\langle P_z^2 \rangle \\
- [D_K + 2R_6]\langle P_z^4 \rangle + 2\sigma\delta_J[\langle P_z^2 \rangle - W]J(J+1) \\
+ 4R_5\sigma[\langle P_z^2 \rangle W - \langle P_z^4 \rangle] + 4R_6\sigma^2[\langle P_z^4 \rangle - 2\langle P_z^2 \rangle W + W^2] \\
+ H_{JK}J^2(J+1)^2\langle P_z^2 \rangle + H_{KJ}J(J+1)\langle P_z^4 \rangle,
\end{aligned} \tag{1}$$

where

$$E_r = \frac{1}{2}(B+C)J(J+1) + [A - \frac{1}{2}(B+C)]W(b_p), \tag{2}$$

$$\sigma = -1/b_p = (2A - B - C)/(B-C), \tag{3}$$

and A, B, and C are the rotational constants in order of decreasing magnitude.  $E_r$  is the rigid rotor energy and  $W \equiv W(b_p)$  is the Wang reduced energy. J is the quantum number corresponding to the total angular momentum operator with molecule-fixed z-component  $P_z$ . General formulas for the expectation values  $\langle P_z^2 \rangle$  and  $\langle P_z^4 \rangle$  have been given in Ref. 14. The D's, R's, and  $\sigma_J$  are linear combinations of the  $\tau$ 's, coefficients of centrifugal distortion.<sup>14</sup>

The absolute intensity of an absorption line corresponding to a transition between initial and final states with quantum numbers  $n''$  and  $n'$ , resp., is<sup>16</sup>

$$I_{n''n'} = \frac{8\pi^3 N g_{n''} v [1 - \exp(-hv/kT)] \exp(-E_{n''}/kT)}{3hcp \sum_{n''} g_{n''} \exp(-E_{n''}/kT)} \times |\mu_{n''n'}|^2, \tag{4}$$

where N is the number of molecules per  $\text{cm}^{-3}$ ,  $v \equiv (E_{n'} - E_{n''})/h$  is the central frequency of the line, and  $g_{n''}$  is the statistical weight factor. The quantity  $\mu_{n''n'}$  is the expectation value of the transition dipole moment, p and T are the gas pressure and temperature, resp., and k, h, and c are universal constants. Eq. (4) can be simplified by collecting into a single constant C all quantities which are essentially unchanged for all the lines of a particular vibration-rotation band. Also, expressing  $|\mu_{n''n'}|^2$  in terms of  $S_{R''R}^g$ , (the square of the direction cosine matrix element along the molecule-fixed g axis) and dipole-moment derivatives,<sup>17</sup> we obtain for the case of a rigid rotor

$$I_{n''n'}^o = C g_{n''} v_i [1 - \exp(-hv_i/kT)] [\exp(-E_{R''}/kT) \left( \frac{\pi}{4\pi c v_i^o} \right) \sum_g S_{R''R'}^g \left( \frac{\partial \mu_g}{\partial Q_i} \right)^2], \quad (5)$$

where R represents the rotational quantum numbers, and  $Q_i$  is the normal coordinate for the fundamental vibration  $v_i$ . The band center is denoted by  $v_i^o$ .

For a given fundamental vibration, Eq.(5) reduces further to

$$I_{n''n'}^o = C' g_{n''} \left( \frac{v_i}{v_i^o} \right) [1 - \exp(-hv_i/kT)] [\exp(-E_{R''}/kT) \sum_g S_{R''R'}^g], \quad (6)$$

where

$$C' = \frac{\pi N}{3c^2 p \sum_{n''} g_{n''} \exp(-E_{n''}/kT)} \left[ \left( \frac{\partial \mu_a}{\partial Q_i} \right)^2 \text{ or } \left( \frac{\partial \mu_b}{\partial Q_i} \right)^2 \right]. \quad (7)$$

The factorization of Eq.(5) into Eqs.(6) and (7) is a consequence of the fact that the fundamental bands of planar asymmetric rotors such as  $\text{SO}_2$  are of only two types. These are denoted by A (as in  $v_3$ ) or B (as in  $v_1$  and  $v_2$ ) for which the dipole-moment derivative is along the axis of least (a-axis) or intermediate (b-axis) moment of inertia. Thus

$$\sum_g \left( \frac{\partial \mu_g}{\partial Q_i} \right)^2 = \left( \frac{\partial \mu_a}{\partial Q_i} \right)^2 \text{ or } \left( \frac{\partial \mu_b}{\partial Q_i} \right)^2. \quad (8)$$

For computing line intensities  $I_{n''n'}^o/C'$  and line positions  $(E_{n''} - E_{n'})/h$ , we have used the computer program originally written by Pierce and modified by Eggers.<sup>18</sup> This program is very compact and fast.<sup>19</sup> In it, the wave-number range of the entire band is divided into a large number of intervals, each of which may be taken as approximately half a resolution element. The intensity of each transition is assigned to the appropriate interval. When these assignments are completed, the intensity in each interval is distributed over adjacent intervals according to a Gaussian function which takes into account the finite width of the absorption lines. We have used, instead, a triangular distribution function with base equal to twice our experimental slit width. We found that this approach gave the best

<sup>a</sup>The first nine values are taken from Ref. 4, the next three are calculated from Eqs. (9-11) of Ref. 15, and the remaining seven are calculated from relations (36) of Ref. 14.

<sup>b</sup>Dimensionless, see Eq. (3).

<sup>c</sup>The values for  $v_1$  are taken from Ref. 6, and those for  $v_2$  and  $v_3$  are taken from Ref. 2.

agreement between the calculated theoretical spectrum and the overall detailed appearance of our experimental spectrum.

Rotational and centrifugal distortion constants, in the ground and excited vibrational states of  $\text{SO}_2$ , used in the computer program have been taken from far-infrared<sup>4</sup> and microwave<sup>2,6</sup> spectra. These values and the remaining derived values, calculated from the relations in Refs. 14 and 15, are given in Table II. The computer program takes into account the fact that in the ground state of  $\text{SO}_2$  only symmetric levels occur because of  $C_{2v}$  symmetry and zero spin of the  $^{16}\text{O}$  nuclei. The initial values for the three band centers were taken from the work of Shelton *et al.*<sup>1</sup>. These values were later adjusted so that the experimental and theoretical spectra would match.

The dipole moment derivatives for the fundamentals were calculated in the following way. Equation (6) was summed over all transitions having  $J \leq 60$ . Previously measured experimental band intensities,<sup>20-23</sup> and a projected value,<sup>8</sup> were taken for  $\sum_{n''} I^o_{n''n''}$ . Our calculated line intensities were used for the sum on the right-hand side of Eq.(6), so that  $C'$  was determined. The sum over  $n''$  in Eq.(7) could be factored, to a good approximation, into a vibrational and a rotational partition function which were readily evaluated from Eqs.(V,17) and (V,29), resp., of Ref. 12. Finally, from the value of  $C'$  obtained using Eq.(6), the dipole moment derivatives were deduced from Eq.(7). As the derivatives occur squared in Eq.(7), only their absolute values could be determined by this method.

#### IV. RESULTS

The results of our experimental and theoretical studies of the fundamental infrared bands of  $^{32}\text{S}^{16}\text{O}_2$  are summarized in Figs. 1-3 and Tables III-VI. A representative portion of these results have also been presented in Ref. 24. The experimental conditions were given in Table I. Spectral resolution in the  $1100-1400 \text{ cm}^{-1}$  region for  $\nu_1$  and  $\nu_3$  was typically about  $0.12 \text{ cm}^{-1}$ , with isolated instances of  $0.10 \text{ cm}^{-1}$  or better. In the  $475-600 \text{ cm}^{-1}$  region for  $\nu_2$ , resolution was characteristically  $0.25 \text{ cm}^{-1}$ , and occasionally  $0.20 \text{ cm}^{-1}$  or better. In the Figures, the upper tracings are the measured experimental spectra, with percent absorption shown in the right-hand vertical scales. It should be noted that both the measured spectra and the right-hand scales are displaced upward by the same amount,

so that 0% absorption denotes the experimental base line.

Our calculated theoretical spectra are also represented in Figs. 1-3. These spectra are the lower tracings, with relative intensity on the left-hand vertical scales. The intensity plotted in the Figures is a normalized distribution of line intensities. This distribution into small intervals was discussed in Sec. III. The normalization, on a linear scale, is made with respect to that distribution of intensities (arbitrarily assigned the value 100 for  $v_1$  and  $v_3$ , and 90 for  $v_2$ ) which is the maximum for all the intervals in a given band. As can be seen in the Figures, there is good agreement between the theoretical and experimental spectra.

In Tables III-V, the observed and computed spectral line positions are compared. Only the stronger theoretical transitions corresponding to each experimental line peak have been listed in these Tables. (Where there is a blank space in the column of experimental line positions, the adjacent theoretical line position corresponds to the previously tabulated experimental line.) With very few minor exceptions, 97% of the tabulated computed lines fall within  $\pm 0.05 \text{ cm}^{-1}$  of the observed lines. Initial- and final-state quantum number assignments, as well as theoretical line intensities  $I_{n''n'}^{\circ}/C'$  defined by Eq.(6), are given for the computed lines in Tables III-V. The quantum numbers  $K_{-1}$  and  $K_1$  are associated with the projection of the total angular momentum (having quantum number J) on the symmetry axis in, resp., the prolate and oblate symmetric top limiting cases.<sup>12,13</sup>

Experimental and theoretical results for  $v_1$  in the spectral range from 1112.5 to  $1200.0 \text{ cm}^{-1}$  are represented in Fig. 1 and Table III. The selection rules<sup>25</sup> are  $\Delta J = 0, \pm 1$ ;  $J = 0 \leftrightarrow J = 0$ ; and  $\Delta K_{-1} = \pm 1, \pm 3, \dots$ . Approximately 450 observed lines have now been assigned. The band center for  $v_1$  has been determined in the present work to be  $1151.65 \pm 0.10 \text{ cm}^{-1}$ . Earlier infrared observations yielded the values 1152 (Ref. 26), 1151.38 (Refs. 27 and 1),  $1152 \pm 1$  (Ref. 28), and  $1151.2 \pm 0.2 \text{ cm}^{-1}$  (Ref. 29). Most recently, Hinkley et al.,<sup>8</sup> using very high resolution (line width less than  $10^{-5} \text{ cm}^{-1}$ ) techniques, have found a value of  $1151.71 \pm 0.01 \text{ cm}^{-1}$  in excellent agreement with our result, to within our experimental error. We have also compared our calculated line positions, taking into account the  $0.06 \text{ cm}^{-1}$  difference in band centers, to the several rather isolated

TABLE III

COMPARISON OF EXPERIMENTAL AND THEORETICAL SPECTRAL LINE POSITIONS, WITH QUANTUM NUMBER ASSIGNMENTS, FOR THE  $v_1$  BAND OF  $^{32}\text{S}^{16}\text{O}_2$  CENTERED AT  $1151.65 \pm 0.10 \text{ cm}^{-1}$ .  
LINE INTENSITIES [SEE SEC.III, ESPECIALLY EQ. (6)] ARE COMPUTED AT  $300^\circ\text{K}$ .

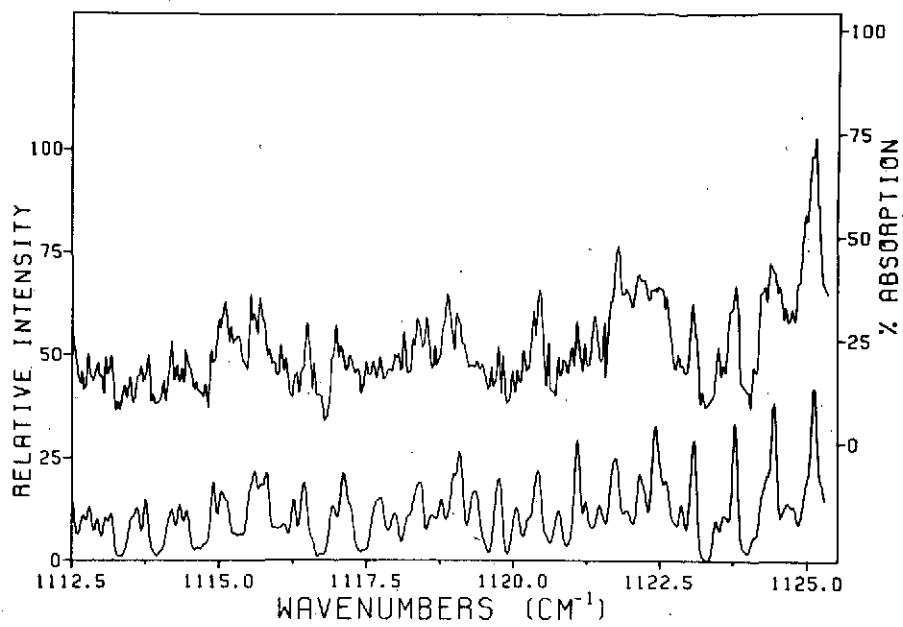

Fig. 1(a). Experimental and theoretical spectra of  $v_1$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1112.5$  to  $1125.0 \text{ cm}^{-1}$ .

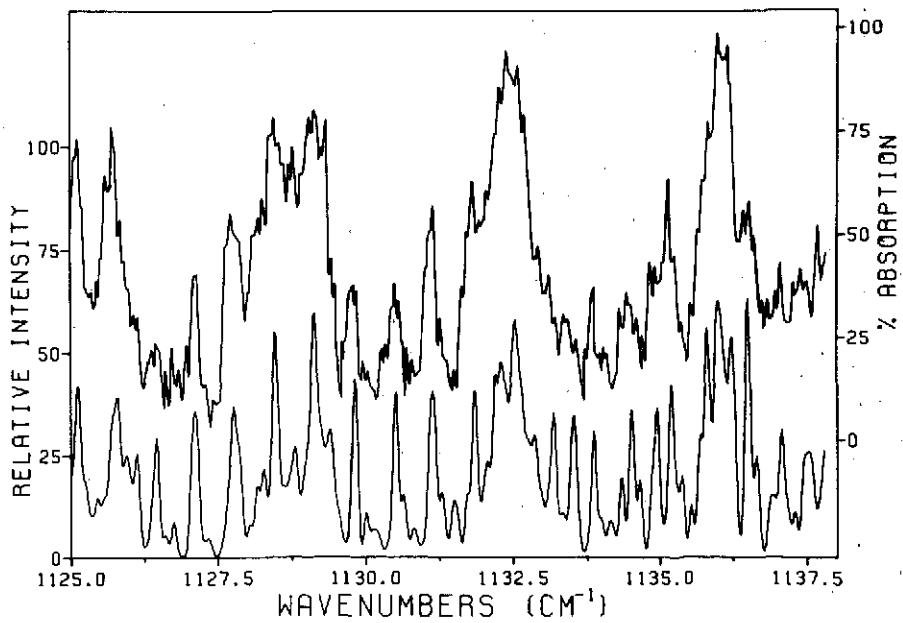

Fig. 1(b). Experimental and theoretical spectra of  $v_1$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1125.0$  to  $1137.5 \text{ cm}^{-1}$ .

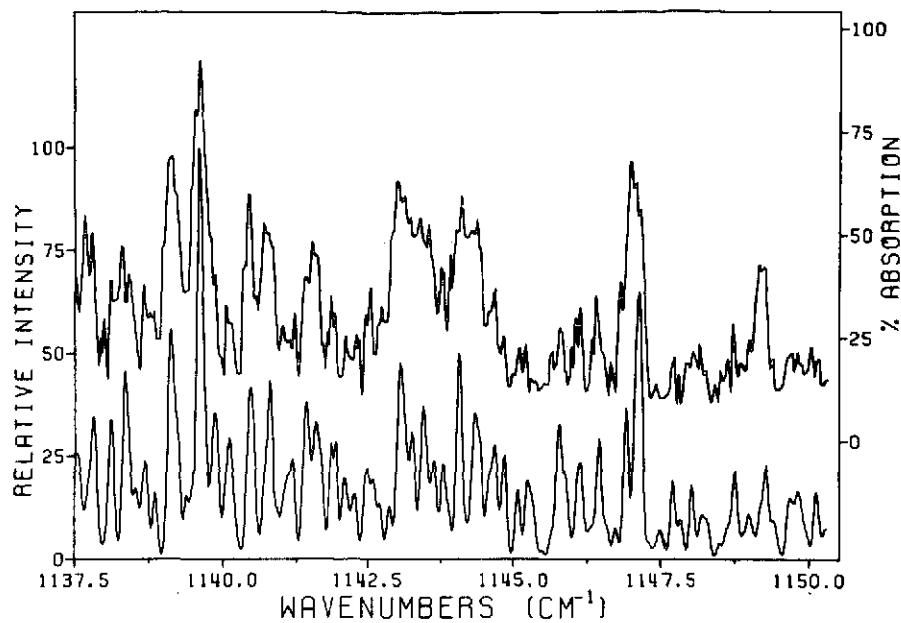

Fig. 1(c). Experimental and theoretical spectra of  $\nu_1$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1137.5$  to  $1150.0 \text{ cm}^{-1}$ .

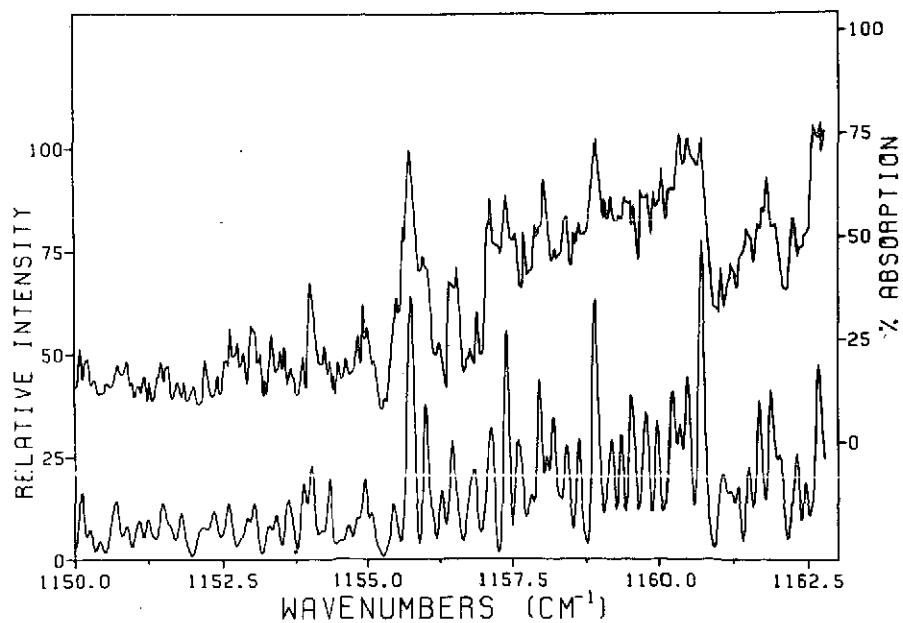

Fig. 1(d). Experimental and theoretical spectra of  $\nu_1$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1150.0$  to  $1162.5 \text{ cm}^{-1}$ .

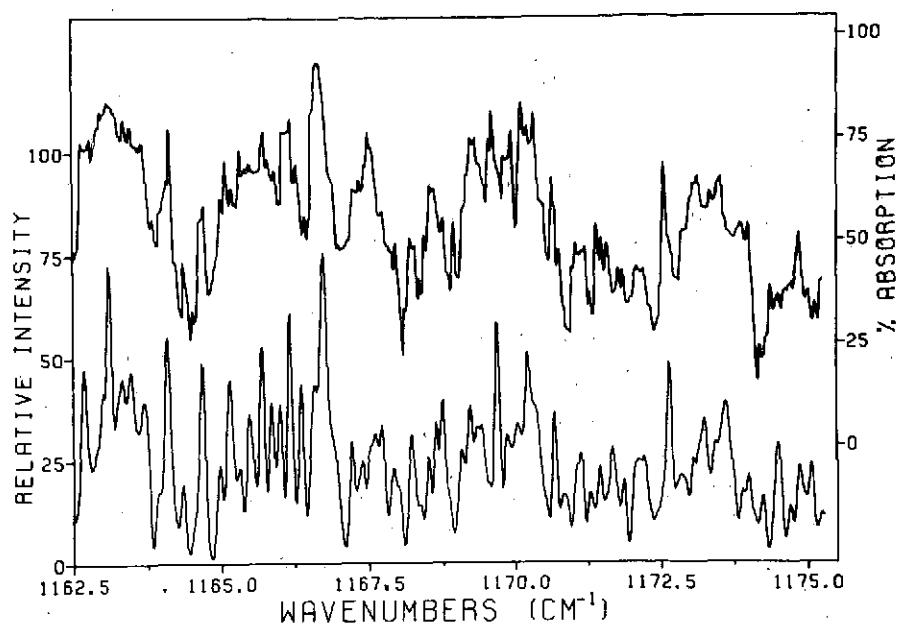

Fig. 1(e). Experimental and theoretical spectra of  $v_1$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1162.5$  to  $1175.0 \text{ cm}^{-1}$ .

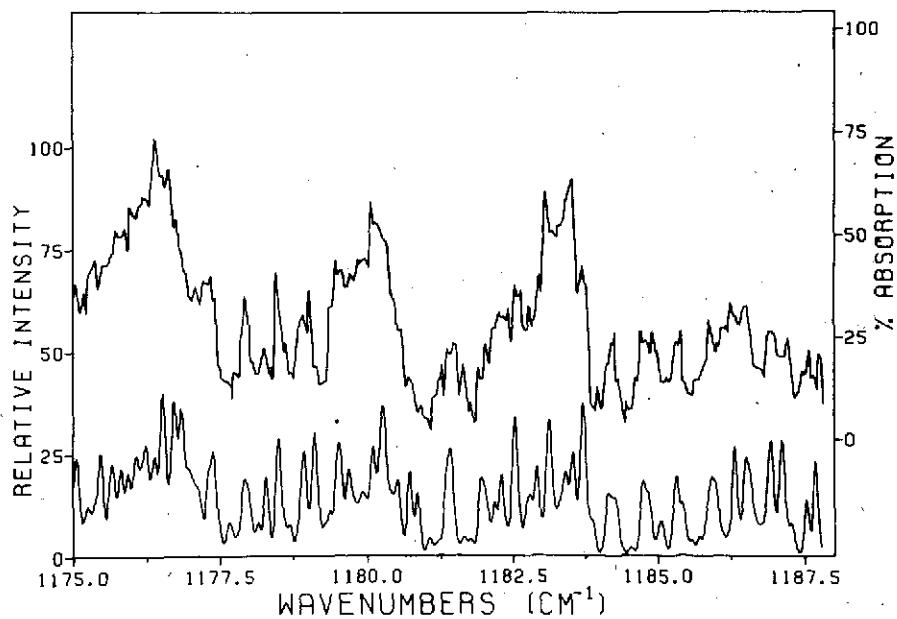

Fig. 1(f). Experimental and theoretical spectra of  $v_1$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1175.0$  to  $1187.5 \text{ cm}^{-1}$ .

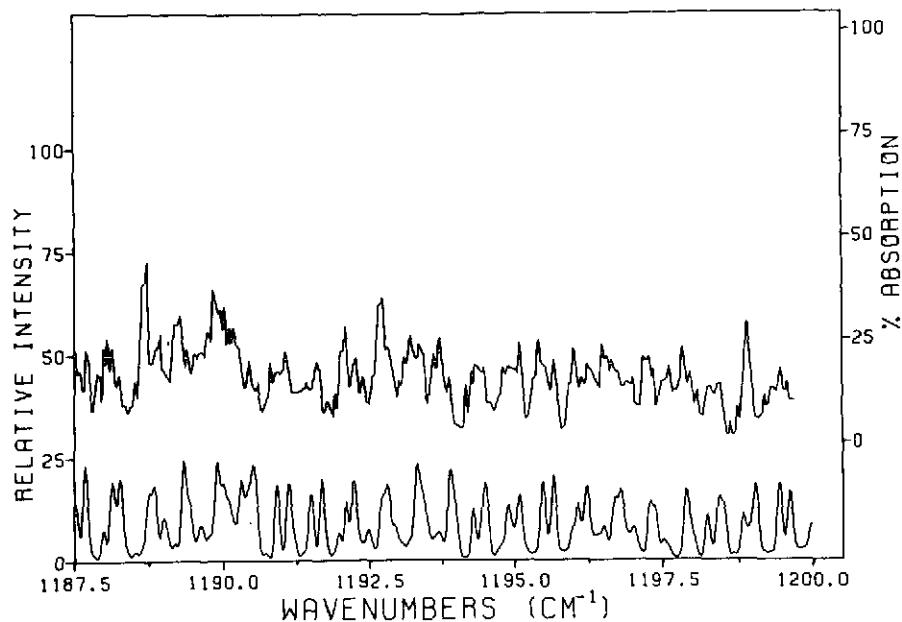

Fig. 1(g). Experimental and theoretical spectra of  $v_1$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range 1187.5 to 1200.0  $\text{cm}^{-1}$ .

lines in Table I of Ref. 8, and have determined that the two sets of values agree to  $0.01 \text{ cm}^{-1}$  except for a single line with  $J = 30$  for which the apparent discrepancy is only  $0.02 \text{ cm}^{-1}$ . Subsequently, from a more extensive tabulation provided by Hinkley [Appendix B of Ref. 30] we found that for all lines with  $J \leq 46$ , of which there are 78, the maximum difference in the calculated line positions was  $0.02 \text{ cm}^{-1}$ . These differences may be attributed to the small disparities in assumed excited-state centrifugal distortion constants.

In Fig. 2 and Table IV, we have compared our experimental and theoretical results for  $v_2$  in the spectral range from 470 to  $590 \text{ cm}^{-1}$ . The selection rules for this band<sup>25</sup> are the same as those for  $v_1$ , described above. Because of the lower resolution available in the  $v_2$  region, we have been able to assign only approximately 180 observed lines. Strong well-defined peaks in Fig. 2 correspond to Q sub-branches. A sub-branch, in the case of a nearly prolate symmetric top, is characterized by a constant value of  $K_{-1}$  and the parity of the initial state. Individual lines in these sub-branches are in most cases unresolved. In Table IV, the subscripts to Q denote the changes in  $K_{-1}$  and  $K_1$ . The initial state of the transitions is given in parentheses. For low values of  $K_{-1}$ , the even- and odd-parity

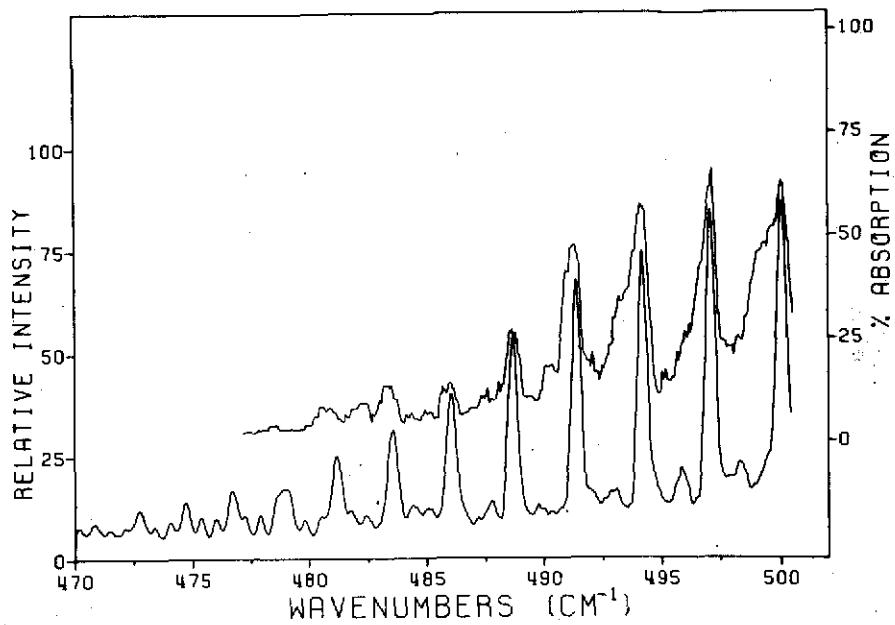

Fig. 2(a). Experimental and theoretical spectra of  $v_2$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $470$  to  $500\text{ cm}^{-1}$ .

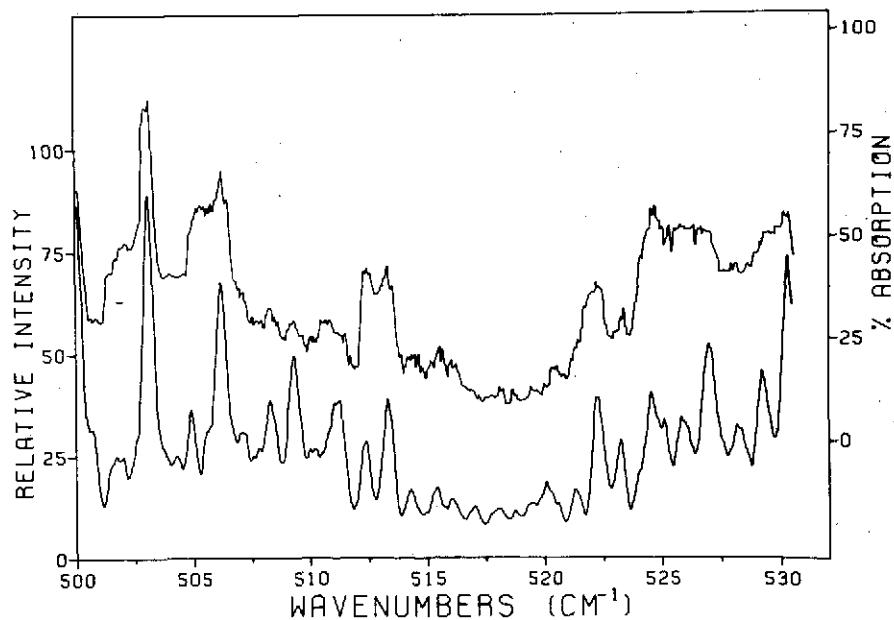

Fig. 2(b). Experimental and theoretical spectra of  $v_2$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $500$  to  $530\text{ cm}^{-1}$ .

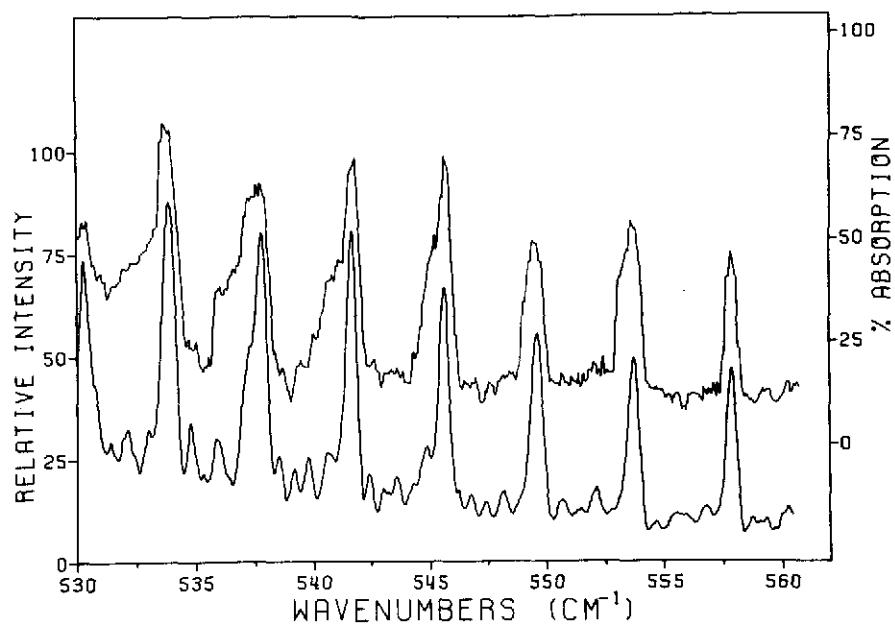

Fig. 2(c). Experimental and theoretical spectra of  $\nu_2$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $530$  to  $560\text{ cm}^{-1}$ .

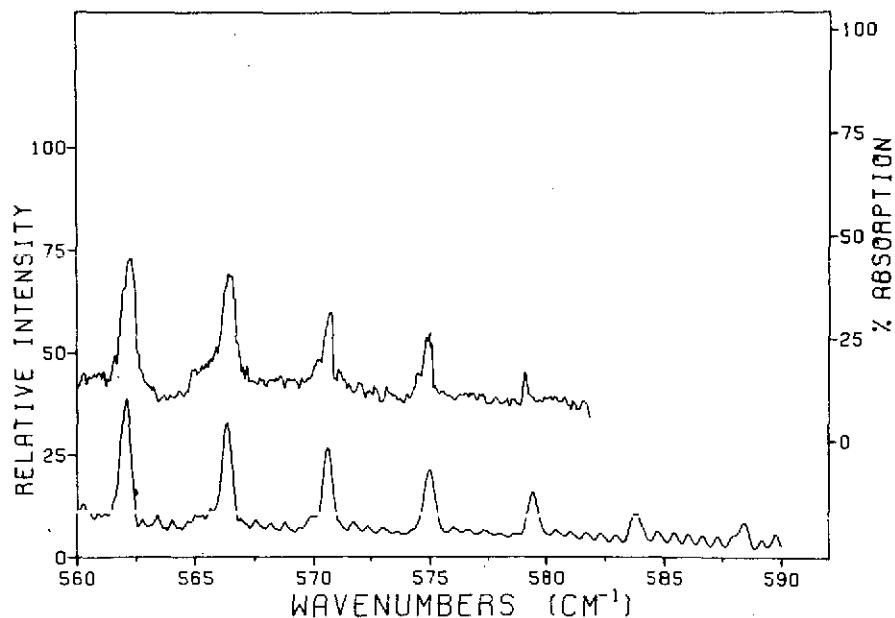

Fig. 2(d). Experimental and theoretical spectra of  $\nu_2$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $560$  to  $590\text{ cm}^{-1}$ .

TABLE IV

COMPARISON OF EXPERIMENTAL AND THEORETICAL SPECTRAL LINE POSITIONS, WITH QUANTUM NUMBER ASSIGNMENTS, FOR THE  $v_2$  BAND OF  $^{32}\text{S}^{16}\text{O}_2$  CENTERED AT  $517.75 \pm 0.10 \text{ cm}^{-1}$ . LINE INTENSITIES [SEE SEC. III, ESPECIALLY EQ. (6)] ARE COMPUTED AT  $300^\circ\text{K}$ . SEE SEC. III FOR Q SUB-BRANCH NOTATION.

sub-branches (corresponding to even- and odd-J transitions, resp., for  $^{32}\text{S}^{16}\text{O}_2$ ) form two separate peaks in a Q sub-branch. As an example, the observed line positions in Table IV at 508.26 and 509.30  $\text{cm}^{-1}$  correspond to the  $^0\text{Q}_{\frac{1}{2}}(J,3,K_1)$  sub-branch and its even-J analog, resp. The left superscripts denote odd and even parity, resp., of the initial states; and the selection rules are explicitly  $\Delta J = 0$ ,  $\Delta K_{-1} = -1$  ( $K_{-1} = 3 + 2$  in this example), and  $\Delta K_1 = +1$ . In the particular cases of  $^0\text{Q}_{\frac{1}{2}}(J,1,K_1)$  and  $^0\text{Q}_{\frac{1}{2}}(J,0,K_1)$ , both of which have only even sub-branches, it has been possible to resolve several individual transitions.

The observed positions of the Q sub-branches in the present work agree with those given previously by Shelton *et al.*<sup>1</sup> We have determined the band center of  $v_2$  to be at  $517.75 \pm 0.10 \text{ cm}^{-1}$ . This value may be compared with the earlier results: 524 (Ref. 26), 517.84 (Ref. 27), 517.69 (Ref. 1), and  $518.0 \pm 0.5 \text{ cm}^{-1}$  (Ref. 28).

The experimental and theoretical results for  $v_3$  in the spectral range from 1327.5 to 1390.0  $\text{cm}^{-1}$  are represented in Fig. 3 and Table V. The selection rules,<sup>25</sup> different from those for  $v_1$  and  $v_2$ , are  $\Delta J = 0, \pm 1$ ;  $J = 0 \leftrightarrow J = 0$ ; but  $\Delta K_{-1} = 0, \pm 2, \dots$ ; and  $\Delta K_1 = \pm 1, \pm 3, \dots$ . Because of the relatively large number of strong, closely spaced lines in  $v_3$ ,

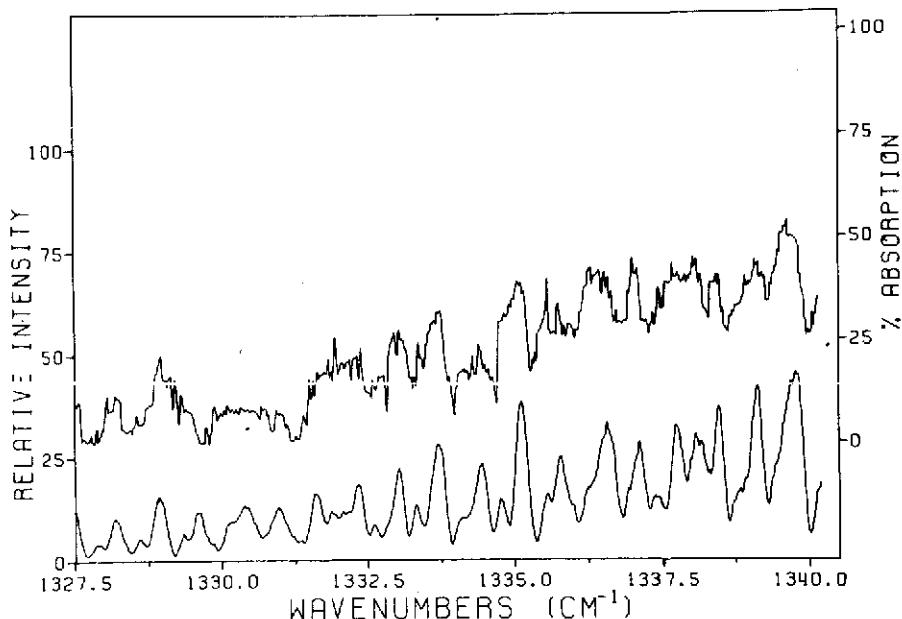

Fig. 3(a). Experimental and theoretical spectra of  $v_3$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range 1327.5 to 1340.0  $\text{cm}^{-1}$ .

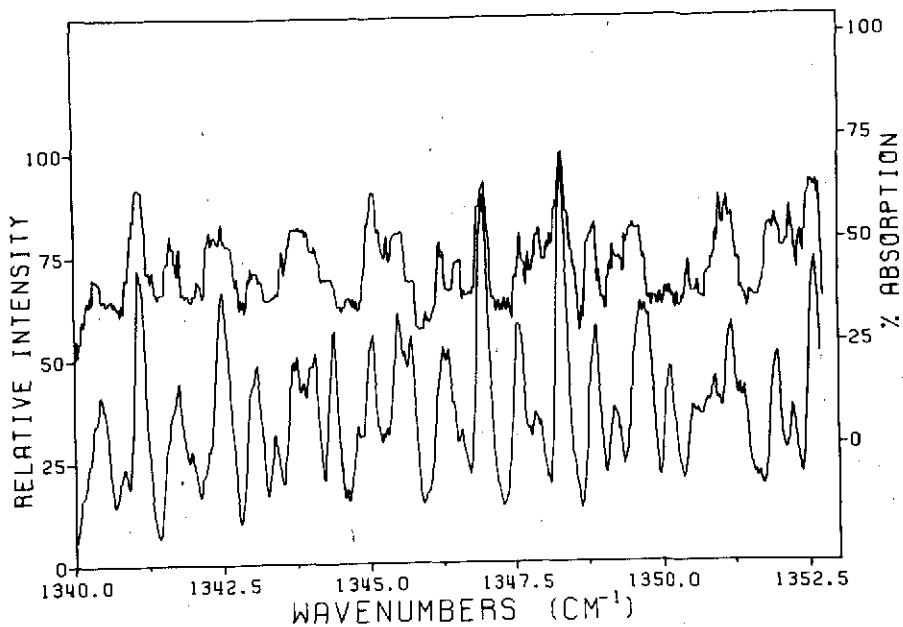

Fig. 3(b). Experimental and theoretical spectra of  $v_3$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1340.0$  to  $1352.5 \text{ cm}^{-1}$ .

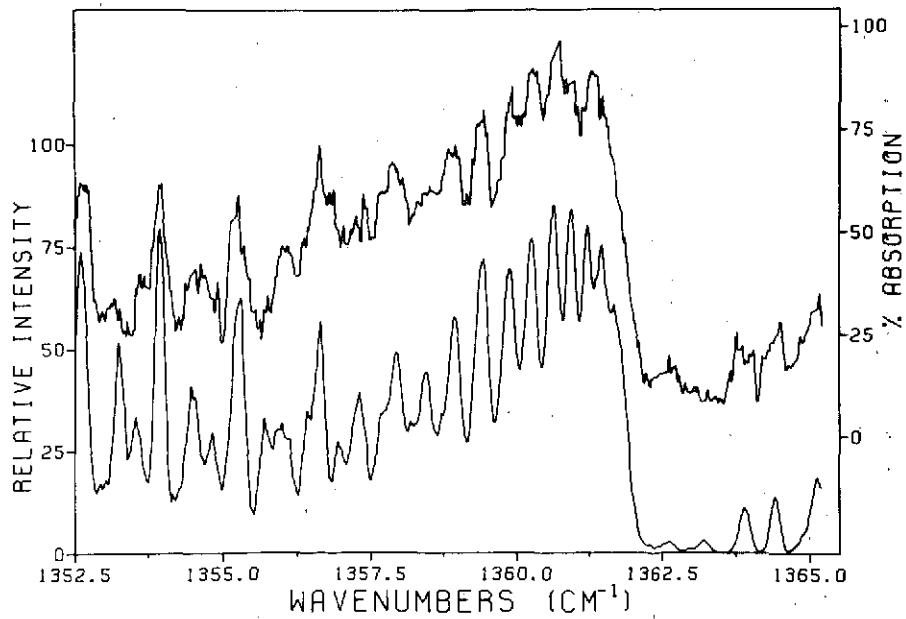

Fig. 3(c). Experimental and theoretical spectra of  $v_3$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1352.5$  to  $1365.0 \text{ cm}^{-1}$ .

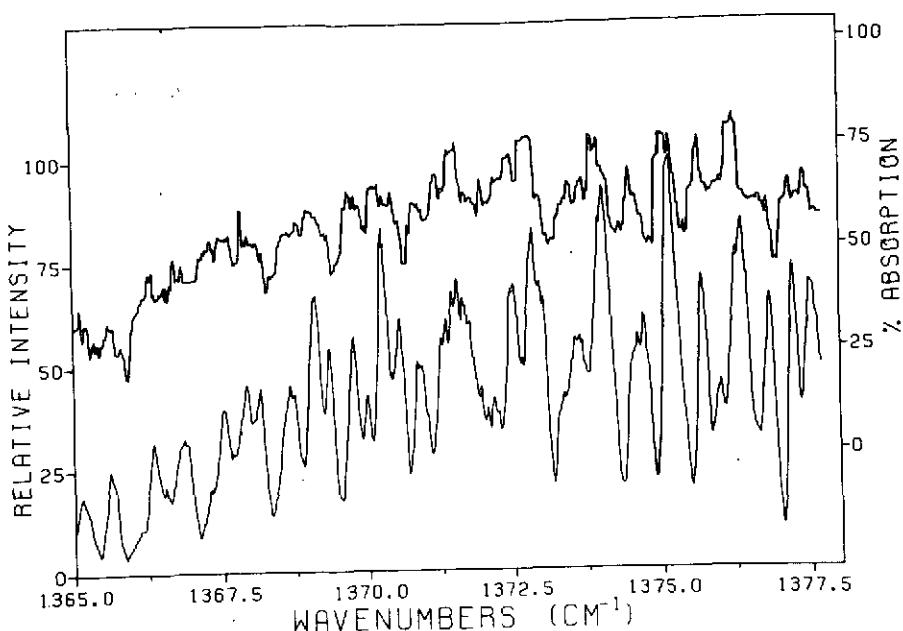

Fig. 3(d). Experimental and theoretical spectra of  $v_3$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1365.0$  to  $1377.5 \text{ cm}^{-1}$ .

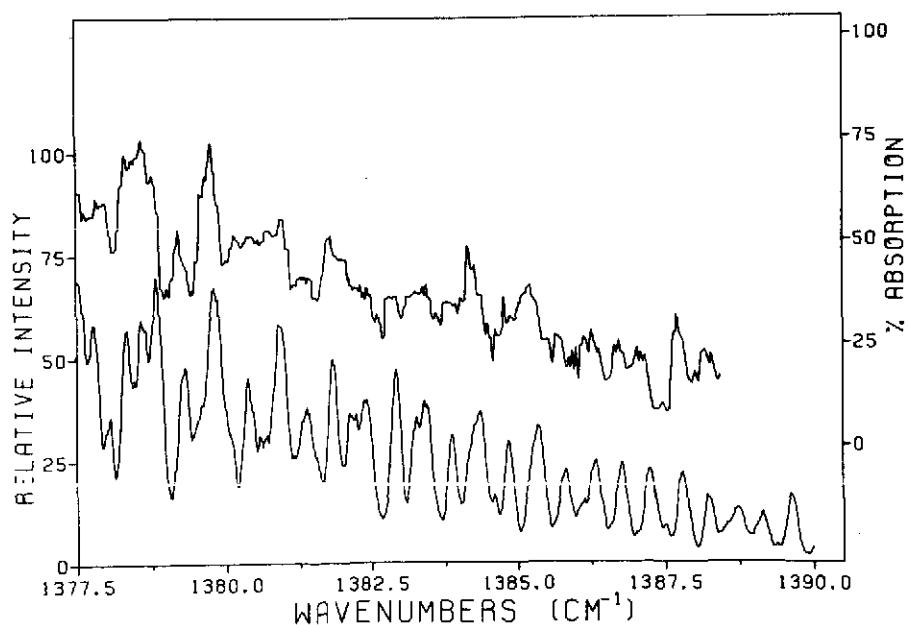

Fig. 3(e). Experimental and theoretical spectra of  $v_3$  band of  $^{32}\text{S}^{16}\text{O}_2$  in range  $1377.5$  to  $1390.0 \text{ cm}^{-1}$ .

TABLE V

COMPARISON OF EXPERIMENTAL AND THEORETICAL SPECTRAL LINE POSITIONS, WITH QUANTUM

NUMBER ASSIGNMENTS, FOR THE  $v_3$  BAND OF  $^{32}\text{S}^{16}\text{O}_2$  CENTERED AT  $1362.00 \pm 0.10 \text{ cm}^{-1}$ .

LINE INTENSITIES [SEE SEC. III, ESPECIALLY EQ. (6)] ARE COMPUTED AT 300°K.

we have assigned only the approximately 250 observed peaks which are either individual or consist of a small number of closely spaced transitions. The band center for  $\nu_3$  in the present work has been determined as  $1362.00 \pm 0.10$   $\text{cm}^{-1}$ . Previously obtained values were 1361 (Ref. 26), 1361.50 (Ref. 27), 1361.76 (Ref. 1),  $1360.5 \pm 0.5$  (Ref. 28), and  $1360.8 \text{ cm}^{-1}$  (Ref. 29).

Finally, we have estimated the absolute values of the dipole moment derivatives<sup>31</sup> for all three infrared-active fundamentals of  $^{32}\text{S}^{16}\text{O}_2$ . Our analysis, using Eqs.(6) and (7), was described in detail in Sec. III. The results are shown in Table VI. The  $\nu_1$  band intensity of Hinkley *et al.*<sup>8</sup> was an average of the projected values which were obtained by dividing the intensities of ten measured lines by their respective calculated fractional contributions to the band.

TABLE VI  
DIPOLE MOMENT DERIVATIVES FOR THE FUNDAMENTALS OF  $^{32}\text{S}^{16}\text{O}_2$

Band	Sum of Calculated Line Intensities (dimensionless)	Measured Band Intensity (in $10^{10} \text{ sec}^{-1} \text{ cm}^{-1}$ STP)	Dipole Moment Derivative <sup>f</sup> (in esu $\text{g}^{-1/2}$ )
$\nu_1$	5227.9	$278 \pm 28^a$	$57.8 \pm 3.0$
		$317 \pm 8^b$	$61.7 \pm 0.8$
		$350 \pm 20^c$	$64.8 \pm 1.9$
		$288 \pm 16^d$	$58.9 \pm 1.7$
		$299 \pm 16^e$	$59.9 \pm 1.6$
$\nu_2$	5288.6	$348 \pm 35^a$	$64.3 \pm 3.3$
		$376 \pm 20^b$	$66.8 \pm 1.8$
		$360 \pm 30^c$	$65.4 \pm 2.8$
$\nu_3$	5742.3	$2520 \pm 252^a$	$166.0 \pm 9.0$
		$2560 \pm 70^b$	$167.3 \pm 2.3$
		$2640 \pm 80^c$	$169.9 \pm 2.6$
		$2437 \pm 161^e$	$163.1 \pm 5.5$

<sup>a</sup>From Ref. 20.

<sup>b</sup>From Ref. 21.

<sup>c</sup>From Ref. 22.

<sup>d</sup>From Ref. 8.

<sup>e</sup>From Ref. 23.

<sup>f</sup>As discussed in Sec. III, only the absolute value can be determined here.

## V. DISCUSSION

There is considerable value, from a fundamental spectroscopic viewpoint, in making high-resolution studies of gases like  $\text{SO}_2$ . Such studies would permit a more complete determination of vibration-rotation line positions and intensities, as well as quantum-number assignments, in all three fundamentals. Further, it would be possible to measure line-shapes and line-broadening parameters as a function of vibration and/or rotation quantum numbers. Some of these experimental and theoretical studies are in progress, and some are anticipated in our laboratory in the near future.

We also plan to investigate overtone and combination bands of  $\text{SO}_2$ . A more precise determination of the band center of  $2\nu_2$  is important to an understanding of possible lasing mechanisms<sup>32</sup> in  $\text{SO}_2$ , associated with Fermi interactions between energy levels in  $\nu_1$  and  $2\nu_2$ . In another context, it is possible that the  $\nu_1 + \nu_3$  band of terrestrial  $\text{SO}_2$  may appear in solar spectra,<sup>33</sup> and be susceptible to analysis there.

Sulfur dioxide plays a serious role as a pollutant in the terrestrial atmosphere.<sup>34</sup> High-resolution infrared spectroscopy is a possible technique for the remote detection and monitoring of  $\text{SO}_2$  in situ. For example, monochromatic laser emissions may be useful for studying terrestrial  $\text{SO}_2$  in absorption. We have found three relatively isolated and moderately strong lines in our laboratory spectra, with observed positions at 561.67, 1347.33, and  $1365.60\text{ cm}^{-1}$  (see Tables IV and V) which fall close to observed laser oscillations<sup>35</sup> in pure neutral neon, Ne I. Although the spectral coincidences are not exact for the first two lines, nevertheless the spectral broadening by air will produce sufficient overlapping of the lines in question.<sup>36</sup>

## ACKNOWLEDGMENTS

We are grateful to Prof. W. H. Fletcher for several helpful discussions, and for a critical reading of this manuscript. Prof. D. F. Eggers, Jr. provided a computer program, developed by Dr. L. Pierce and modified by Prof. Eggers, which was of considerable value in our calculations. Dr. E. D. Hinkley kindly sent us preprints of Refs. 8 and 9. We thank Mr. Glen H. Cunningham of our Electronics Shop for his generous and skillful technical assistance. Mrs. Janice Hemsley typed the manuscript with accuracy and patience. We appreciate the time provided by The University of Tennessee Computing Center on the IBM/360-65 system.
